

Optimisation sous contrainte

1A Enseem NRJ

Objectif : Programmation et illustration graphique de la progression des algorithmes du gradient, gradient projeté et Uzawa.

Livrable : Compte-rendu par binômes en fin de séance (4h).

1 Implémentation de l'algorithme du gradient

L'énergie dépensée par un procédé industriel lors d'un cycle de fonctionnement est paramétré par la fonction :

$$f(x, y) = 3(1 - x)^2 e^{-(x^2) - (y+1)^2} - 10\left(\frac{x}{5} - x^3 - y^5\right) e^{(-x^2 - y^2)} - \frac{1}{3} e^{-(x+1)^2 - y^2} + 0.5(x^2 + y^2)$$

où x et y sont deux paramètres intervenant sur ce cycle. On souhaite déterminer les valeurs de x et y permettant de minimiser la dépense d'énergie. Une première approche consiste à utiliser un algorithme du gradient à pas fixe.

- Analyser et tester le programme naïf (gradient à pas fixe) ci-dessous pour différents pas et positions initiales prises sur un cercle de rayon 3 (Insérer une boucle for).

Programme matlab de l'algorithme du gradient à pas fixe : (faire un copier coller)

```
clear all
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% Affichage de la fonction
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
[x,y]=meshgrid(-3:.1:3,-3:.1:3);

z = 3*(1-x).^2.*exp(-(x.^2) - (y+1).^2) ...
    - 10*(x/5 - x.^3 - y.^5).*exp(-x.^2-y.^2) ...
    - 1/3*exp(-(x+1).^2 - y.^2)+0.5*(x.^2+y.^2);

figure(1)
clf
hold on
surfc(x,y,z)
view(3)
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% Initialisation

    % Affichage progression de X
    %%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
    x=X(1);
    y=X(2);
    z=3*(1-x).^2.*exp(-(x.^2) - (y+1).^2) ...
        - 10*(x/5 - x.^3 - y.^5).*exp(-x.^2-y.^2) ...
```

```

- 1/3*exp(-(x+1).^2 - y.^2)+0.5*(x.^2+y.^2);

plot3(X(1),X(2),z+0.1,'.r','MarkerSize',15)
view(2)
pause(.1)

%Calcul du gradient
g=[.8*x+x/5+(exp(-(x+1)^2-y^2)*(2*x+2))/3 ...
    +3*exp(-(y+1)^2-x^2)*(2*x-2)+exp(-x^2-y^2)*(30*x^2-2) ...
    -6*x*exp(-(y+1)^2-x^2)*(x-1)^2-2*x*exp(-x^2-y^2)*(10*x^3-2*x+10*y^5);
    .8*y+y/5+(2*y*exp(-(x+1)^2-y^2))/3+50*y^4*exp(-x^2-y^2) ...
    -3*exp(-(y+1)^2-x^2)*(2*y+2)*(x-1)^2 ...
    -2*y*exp(-x^2-y^2)*(10*x^3-2*x+10*y^5)];
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% Mise à jour de X
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
Xold=X;
X=X-rho*g;

test=norm(Xold-X)>precision && compteur<maxiter;
end

if compteur==maxiter
    display('warning: Nombre d"iteration maximum atteint')
end

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% Affichage dernier point
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
x=X(1);
y=X(2);
z=3*(1-x).^2.*exp(-(x.^2) - (y+1).^2) ...
    - 10*(x/5 - x.^3 - y.^5).*exp(-x.^2-y.^2) ...
    - 1/3*exp(-(x+1).^2 - y.^2)+0.5*(x.^2+y.^2);
plot3(X(1),X(2),z+.1,'*g','MarkerSize',15)

```

Remarque : L'expression symbolique du gradient g a été obtenue via la commande :

```

syms x y
z = 3*(1-x).^2.*exp(-(x.^2) - (y+1).^2)...
    - 10*(x/5 - x.^3 - y.^5).*exp(-x.^2-y.^2)...

```

```
- 1/3*exp(-(x+1).^2 - y.^2)+0.5*(x.^2+y.^2);
g=jacobian(z)
```

- Observer (graphiquement) la progression obtenue au cours des itérations. Quelle analyse faites vous des résultats obtenus ? Comment y remédier ?
- On se propose d'adapter le pas à chaque itération afin de garantir la décroissance de la fonction f et la convergence de l'algorithme.

Notons X_k la position, f_k la valeur de f au point X_k et ρ_k la valeur du pas au début de l'itération k . On adapte alors le pas ρ_k à chaque itération suivant le schéma :

$$f_{test} = \min_{\rho \in \{\frac{1}{2}\rho_k, \rho_k, 2\rho_k\}} f(X_k - \rho g(X_k))$$

Si $f_{test} \leq f_k$ alors

$$\rho_{k+1} = \arg \min_{\rho \in \{\frac{1}{2}\rho_k, \rho_k, 2\rho_k\}} f(X_k - \rho g(X_k)) \quad (1)$$

$$X_{k+1} = X_k - \rho_{k+1}g(X_k) \quad (2)$$

sinon

$$X_{k+1} = X_k \quad (3)$$

$$\rho_{k+1} = \rho_k/4 \quad (4)$$

fin si

Modifier le programme matlab pour parvenir à ce résultat.

- Tester le programme réalisé pour différentes positions initiales prises sur un cercle de rayon 3 (faire une boucle for).
- Conclure sur la méthode

2 Implémentation de l'algorithme du gradient projeté

On souhaite à présent que la solution trouvée respecte la contrainte

$$AX \geq b$$

avec $X = (x, y)$, $A = [-1 \ 1]$ et $b = 1$, (les paramètres x et y sont liés entre eux par cette contrainte).

- Le domaine de recherche $K = \{(x, y) : AX \geq b\}$ est il convexe ?
- Déterminer à l'aide des conditions de Kuhn et Tucker, l'opérateur de projection de X sur K ,

$$\Pi_K(X) = \arg \min_{Z \in K} \frac{1}{2} \|X - Z\|^2$$

- Modifier l'algorithme à pas variable pour prendre en compte cette contrainte.

3 Implémentation de l'algorithme d'Uzawa

La contrainte est maintenant définie par :

$$c(X) = y - \cosh(x) + 1 \geq 0$$

- Le domaine de recherche $K = \{(x, y) : y - \cosh(x) + 1 \geq 0\}$ est-il convexe ?
- Afin de ne pas calculer l'opérateur de projection (difficile), formuler le problème dual et mettre en oeuvre l'algorithme d'Uzawa :

$\lambda_0 \in C^+ = \{\lambda : \lambda \geq 0\}$ donné

Pour $k = 0, 1, 2, \dots$

1. Pour λ_k fixé, calculer : $X_k(\lambda_k) = \arg \min_X L(X, \lambda_k)$ (problème sans contrainte)
2. $\lambda_{k+1} = \Pi_{C^+}(\lambda_k - \rho_k c(X_k)) = \max(0, \lambda_k - \rho_k c(X_k))$
3. Retourner en 1 tant que $\|\lambda_{k+1} - \lambda_k\| > \epsilon$.

Remarques : Au point 1, on pourra ré-utiliser l'algorithme du gradient à pas variable des questions précédentes pour minimiser le Lagrangien. Au point 2, on mettra en oeuvre une stratégie de pas variable sur ρ_k comme à la section 2.

- Voici une ébauche de programme :

```
clear all
